## CONTACT

🌐 Personal Page    🌐 GitHub    **in** LinkedIn    ✉ Email: mahdi.gilany@queensu.ca

## SUMMARY

Extensive machine learning and deep learning background, both theoretical and practical

Experienced in designing and implementing deep learning models for real-world problems with most up-to-date software tools

Excellent writing, teamwork, and communication skills acquired from prior industrial and academic experience and research publications

## RESEARCH EXPERIENCE

### Research Assistant

*Medical Informatics Laboratory*

Queen's University

Winter 21–now

My primary research is to develop deep learning models for diagnosing prostate cancer on ultrasound images. In this real-world problem, we are dealing with many medical imaging challenges such as low labeled-data regime, weak labeling, distribution shift, and prediction uncertainty. My project involves in addressing different aspects of this problem.

- *Robust predictions and confident diagnoses* seeks to answer how not to learn spurious features which hurt generalizability on unseen data, and if learned to some extent how to avoid disastrous predictions with uncertainty quantification. Robust predictions are critical in healthcare.
- *Self-supervised ultrasound representation learning* deals with learning abstract representations from readily available unlabeled ultrasound images. It essentially helps alleviating the need for large amount of labeled data, and naturally opens up ways to address weak labeling when combined with Transformers.

### Research Assistant

*Lab of Use-inspired Computational Intelligence*

Rochester Institute of Technology

Fall 19–Winter 21

My primary research was to develop deep learning models from using probabilistic view. I worked on two main projects, probabilistic neural model inference and probabilistic continual learning.

- *Probabilistic neural model inference* deals with finding the most plausible (model posterior distribution) neural architecture warranted by data. It essentially learns neural architecture, i.e., depth and width, with some assumption on the space of models.
- *Probabilistic continual learning* deals with teaching a neural model to continually learn new tasks without forgetting the past. The devised neural model, for each task, learns to update the posterior distribution on weights to not forget the past and neural architecture to increase the capacity of network.
